Periodic orbits are rigidly organized in *any* three-dimensional manifold \mathcal{M}^3 by transversality.

If $\mathcal{M}^3 \subset R^3$, Gauss Linking numbers are useful:

$$\mathcal{M}^3 = D^3; D^2 \times S^1; (I \times S^1) \times S^1.$$

If \mathcal{M}^3 can't be squeezed into R^3 , new tools are needed:

$$\mathcal{M}^3 = (S^1 \times S^1) \times S^1, S^2 \times S^1, f(w, x, y, z) = 0, \dots$$

If a flow is suspended on S^2 what can we expect?

We use the circle map as a model for the sphere map $S^2 \rightarrow S^2$.

All the usual culprits are here.

Constraints

Often constraints exist on a dynamical system

$$\frac{d\mathbf{S}}{dt} = f(\mathbf{S}) \quad e.g. \quad \mathbf{S} \cdot f(\mathbf{S}) = 0$$

Constraints lower the dimension of the phase space.

One class of physical systems includes spins (NMR, spintronics, ...). In such cases the spin length is a conserved quantity and the phase space is the sphere surface $S^2 \subset R^3$.

Driven Constrained Systems

Under periodic driving the dynamical equations are

$$\frac{d\mathbf{S}_i}{dt} = f_i(\mathbf{S}) + A_i \cos(\omega t)$$

The phase space is enlarged to $S^2 \times S^1$.

We need to develop new methods to determine the rigid organization of unstable periodic orbits.

Stroboscopic recordings at $T = 2\pi/\omega$ map the sphere surface into itself, so we can study mappings

$$S^2 \rightarrow S^2$$

?? Sphere Maps ??

We can use *circle* maps as a guide to the study of *sphere* maps.
The classical circle map (Arnold) is

$$\theta' = \omega_0 + \theta + k \sin(\theta)$$

- ① Rigid rotation: ω_0
- ② Linear term: θ
- ③ Nonlinear folding term: $k \sin(\theta)$

This simple map exhibits lots of fun properties.

?? Sphere Maps ??

Another way to construct circle maps involves a simple algorithm.

- ① Start with a curve $s(\theta)$.
- ② Compute the normal to the curve at θ
- ③ Determine the angle of the normal, θ' .

Gauss Map:

$$\theta \rightarrow \theta'$$

Implement the Gauss Map on the classical curve called the limaçon:

$$r(\theta) = 2 + a \cos(\theta)$$

Now apply this algorithm to a sphere. Push your finger into the surface and deform to a spherical limacon

$$r(\theta_1, \theta_2, \dots) = 2 + \sum_{j=1}^d a_j \cos(\theta_j)$$

This produces the map $(\theta, \phi) \rightarrow (\theta', \phi')$.

The map is invertible for $|a_1| + |a_2| < 1$ and is not invertible otherwise. Noninvertible maps have exciting bifurcation structures. These maps depend on 3 rotation parameters and one nonlinear parameter. Several combinations are shown in the following color plots.
