DEFINITION OF A **MICROSTATE**

Example: Binding of RNA polymerase to a DNA target site: a simple ligand-receptor binding.

- *a lattice model* of the solution
- Ω ... number of lattice sites
- L ... number of ligands
- a single receptor

What is a microstate? [see Fig.]

How many possible microstates is there?

(1) receptor is unoccupied:

$$\Omega! / [L! (\Omega - L)!]$$

(2) receptor occupied: $L \rightarrow L - 1$

Figure 6.1 Physical Biology of the Cell (© Garland Science 2009)

Another example of **microstates**: DNA in solution

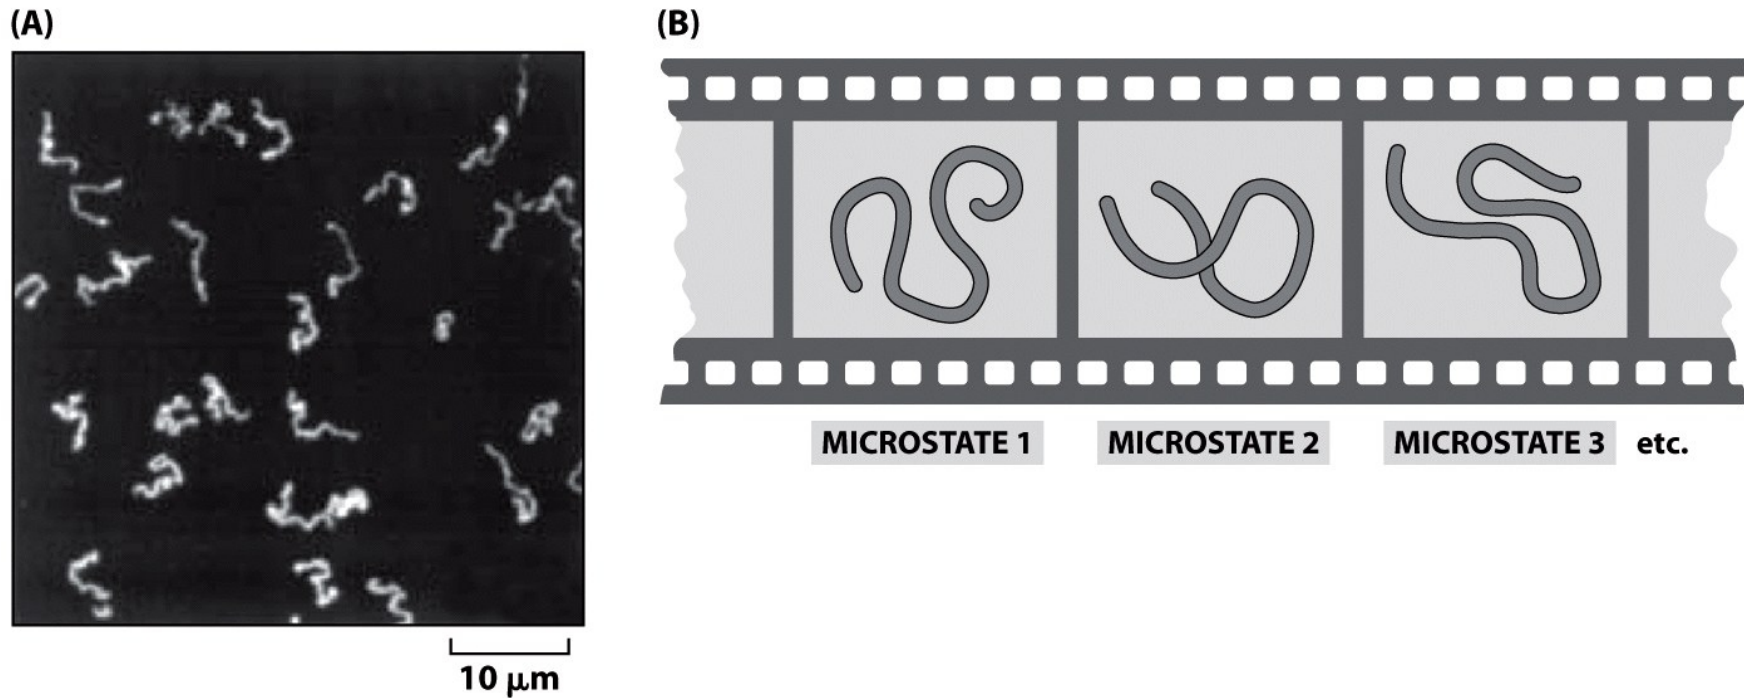

Figure 6.2 Physical Biology of the Cell (© Garland Science 2009)

- (A) fluorescence microscopy image of DNA
- (B) individual microstates of a single DNA molecule

What is **the occurrence probability of each microstate**?
Example: A *two-state* system (ion channel: open versus closed)

Figure 6.3 Physical Biology of the Cell (© Garland Science 2009)

Two state system: only two microstates exist

- the time the ion channel is open versus the time the ion channel is closed can be used to calculate the occurrence probabilities, p_{open} and p_{closed}
- what determines these probabilities?
energies of individual microstates, ϵ_{open} and ϵ_{closed}

The probability of finding a microstate with an energy E_i is

$$p(E_i) = \exp(-E_i/k_B T) / Z$$

The role and identity of Z :

- probabilities need to be normalized: $\sum_i p(E_i) = 1$
- Z is known as *the partition function*

$$Z = \sum_i \exp(-E_i/k_B T) \quad \dots \text{sum over all microstates}$$

Why do we need the probabilities and the partition function?

$$\langle E \rangle = \sum_i E_i p(E_i) = Z^{-1} \sum_i E_i \exp(-E_i/k_B T) \quad \dots \text{calculate the average quantities (e.g. average energy)}$$

Useful expressions in terms of $\beta = (k_B T)^{-1}$

$$\langle E \rangle = - Z^{-1} \partial Z / \partial \beta = - \partial (\ln Z) / \partial \beta$$

Ligand-Receptor Binding:

binding of oxygen to hemoglobin
binding of transcription factors to DNA

How do we calculate the probability of receptor binding?

$$p_{\text{bound}} = \frac{\sum_{\text{states}} \left(\text{grid with 1 bound ligand} \right)}{\sum_{\text{states}} \left(\text{grid with 0 bound ligands} \right) + \sum_{\text{states}} \left(\text{grid with 1 bound ligand} \right)}$$

Figure 6.5 Physical Biology of the Cell (© Garland Science 2009)

There are many microstates in which the receptor is bound
and many microstates in which no binding takes place:
multiplicities of the two states

	STATE	ENERGY	MULTIPLICITY	WEIGHT
(A)		$L\epsilon_{sol}$	$\frac{\Omega!}{L!(\Omega-L)!} \approx \frac{\Omega^L}{L!}$	$\frac{\Omega^L}{L!} e^{-\beta L\epsilon_{sol}}$
(B)		$(L-1)\epsilon_{sol} + \epsilon_b$	$\frac{\Omega!}{(L-1)!(\Omega-L+1)!} \approx \frac{\Omega^{L-1}}{(L-1)!}$	$\frac{\Omega^{L-1}}{(L-1)!} e^{-\beta[(L-1)\epsilon_{sol} + \epsilon_b]}$

Figure 6.4 Physical Biology of the Cell (© Garland Science 2009)

Weight for a situation in which a receptor is bound:

$$\text{weight (bound)} = \exp(-\beta \epsilon_b) \times \sum_{sd} \exp[-\beta(L-1)\epsilon_{sd}]$$

$$\sum_{sd} \exp[-\beta(L-1)\epsilon_{sd}] = \text{multiplicity} \times \exp[-\beta(L-1)\epsilon_{sd}]$$

$$= \Omega! / [(L-1)! (\Omega - L + 1)!] \exp[-\beta(L-1)\epsilon_{sd}]$$

$$\text{weight (bound)} = \Omega! / [(L-1)! (\Omega - L + 1)!] \exp[-\beta \epsilon_b - \beta(L-1)\epsilon_{sd}]$$

$$\text{weight (unbound)} = \Omega! / [L! (\Omega - L)!] \exp[-\beta L \epsilon_{sd}]$$

Partition function:

$$Z(L, \Omega) = \text{weight (bound)} + \text{weight (unbound)}$$

Useful approximation for the case $L \ll \Omega$:

$$\Omega! / (\Omega - L)! = \Omega^L$$

Can be derived using Stirling's approximation: $\ln(N!) = N \ln N - N$

$$\begin{aligned} \ln[\Omega! / (\Omega - L)!] &= \ln \Omega! - \ln(\Omega - L)! \approx \Omega \ln \Omega - \Omega - (\Omega - L) \ln(\Omega - L) + (\Omega - L) \\ &\approx \Omega \ln \Omega - (\Omega - L) \ln(\Omega - L) = \\ \ln[\Omega^\Omega (\Omega - L)^L / (\Omega - L)^{(\Omega - L)}] &\approx \ln[\Omega^\Omega \Omega^L (\Omega - L)^L / (\Omega - L)^\Omega] \approx \\ &\quad \ln \Omega^L \end{aligned}$$

Thus, we can calculate p_{bund} as:

$$\begin{aligned} p_{\text{bund}} &= (L/\Omega) \exp(-\beta \Delta \epsilon) / [1 + (L/\Omega) \exp(-\beta \Delta \epsilon)] \\ p_{\text{bund}} &= (c/c_0) \exp(-\beta \Delta \epsilon) / [1 + (c/c_0) \exp(-\beta \Delta \epsilon)] \end{aligned}$$

Classical result: a competition between energetic and entropic contributions to the free energy: $c/c_0 = 1/2$... half occupancy

Figure 6.6 Physical Biology of the Cell (© Garland Science 2009)

Statistical Mechanics of Gene Expression: RNA polymerase binding at promotor sites

Cells can control transcription and translation: revised central dogma

Figure 6.8 Physical Biology of the Cell (© Garland Science 2009)

Figure 6.7 Physical Biology of the Cell (© Garland Science 2009)

Transcription: a process that begins once the polymerase
Escaped the promotor and moves along the gene (part of DNA)
And results in creation of mRNA molecule (*a transcript*).

Figure 3.9 Physical Biology of the Cell (© Garland Science 2009)

a microscopy image of transcription

Experimental evidence: thousands of RNA polymerase molecules in *E. coli* bound to the DNA promoter sites

Figure 6.9 Physical Biology of the Cell (© Garland Science 2009)

Simplest model of RNA polymerase binding to DNA:

DNA modeled as:

- N_{NS} distinct boxes (NS ... non-specific sites)
- P number of RNA polymerase molecules
(only one molecule per non-specific DNA site)

Partial partition function for non-specific binding:

$$Z_{NS}(P, N_{NS}) = \frac{N_{NS}!}{P! (N_{NS} - P)!} \exp(-\beta P \epsilon_{pd}^{NS})$$

Figure 6.10 Physical Biology of the Cell (© Garland Science 2009)

The total partition function is a sum of two parts:

[no RNAP on promoter] + [one RNAP on promoter]

$$Z(P, N_{\text{NS}}) = Z_{\text{NS}}(P, N_{\text{NS}}) + Z_{\text{NS}}(P-1, N_{\text{NS}}) \exp(-\beta \epsilon_{\text{pl}}^{\text{S}})$$

Probability of one RNAP bound to the promoter site is:

$$p_{\text{bound}} = \frac{\sum_{\text{states}} \left(\text{Diagram of DNA with RNAP on promoter} \right)}{\sum_{\text{states}} \left(\text{Diagram of DNA with RNAP on DNA} \right) + \sum_{\text{states}} \left(\text{Diagram of DNA with RNAP on promoter} \right)}$$

The diagrams illustrate a DNA molecule with multiple binding sites (represented by small circles) and a specific promoter site (indicated by a black rectangle and an arrow). The top diagram shows a single RNAP molecule bound to the promoter. The bottom diagrams show two cases: the first shows RNAP bound to a regular DNA site, and the second shows RNAP bound to the promoter site.

Figure 6.12 Physical Biology of the Cell (© Garland Science 2009)

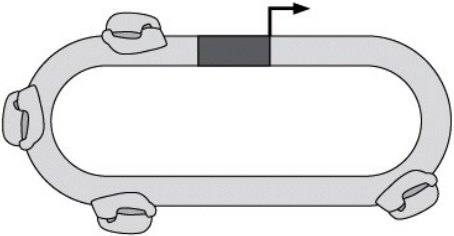

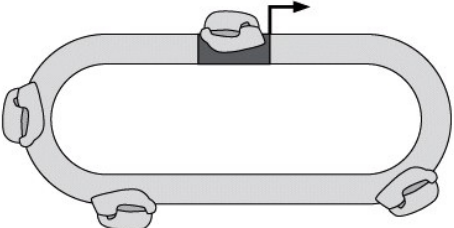

STATE	ENERGY	MULTIPLICITY	WEIGHT (MULTIPLICITY x BOLTZMANN WEIGHT)
	$P \epsilon_{pd}^{NS}$	$\frac{N_{NS}!}{P! (N_{NS}-P)!} \approx \frac{(N_{NS})^P}{P!}$	$\frac{(N_{NS})^P}{P!} e^{-P \epsilon_{pd}^{NS} / k_B T}$
	$(P-1) \epsilon_{pd}^{NS} + \epsilon_{pd}^S$	$\frac{N_{NS}!}{(P-1)! [N_{NS}-(P-1)]!} \approx \frac{(N_{NS})^{P-1}}{(P-1)!}$	$\frac{(N_{NS})^{P-1}}{(P-1)!} e^{-(P-1) \epsilon_{pd}^{NS} / k_B T} e^{-\epsilon_{pd}^S / k_B T}$

Figure 6.11 Physical Biology of the Cell (© Garland Science 2009)

$$\begin{aligned}
 p_{\text{bound}} &= \\
 & Z_{\text{NS}}(P-1, N_{\text{NS}}) \exp(-\beta \epsilon_{\text{pl}}^S) / [Z_{\text{NS}}(P, N_{\text{NS}}) + Z_{\text{NS}}(P-1, N_{\text{NS}}) \exp(-\beta \epsilon_{\text{pl}}^S)] \\
 &= \\
 & [1 + N_{\text{NS}}/P \exp(\beta \Delta \epsilon_{\text{pl}})]^{-1} \\
 & \Delta \epsilon_{\text{pl}} = \epsilon_{\text{pl}}^S - \epsilon_{\text{pl}}^{\text{NS}}
 \end{aligned}$$

The more negative the difference $\Delta \epsilon_{\text{pl}}$, the higher the probability of binding (lac P1: $-2.9 \text{ k}_B \text{T}$; T7 A1: $-8.1 \text{ k}_B \text{T}$).

Figure 6.13 Physical Biology of the Cell (© Garland Science 2009)

Classical derivation of the Boltzmann distribution:

system + reservoir = isolated system maximal entropy principle

Fundamental idea:

probability of finding *a microstate of the system* is proportional to the number of states available to the reservoir when the system is in its specific microstate:

$$p(E_s^I)/p(E_s^{II}) = \frac{W_r(E_{\text{tot}} - E_s^I)}{W_r(E_{\text{tot}} - E_s^{II})}$$

Figure 6.14 Physical Biology of the Cell (© Garland Science 2009)

$$W_{\text{tot}}(E_{\text{tot}} - E_s^I) = 1 \times W_r(E_{\text{tot}} - E_s^I)$$

One state of the system \times all possible
States of the reservoir

$$S = k_B \ln W$$

$$S_r(E_{\text{tot}} - E_s) = S_r(E_{\text{tot}}) - (\partial S_r / \partial E) E_s$$

$$(\partial S_r / \partial E) = 1/T$$

$$p(E_s^I)/p(E_s^{II}) = \exp(-\beta E_s^I)/\exp(-\beta E_s^{II})$$

Relationship between Z and free energy G :

$$G(X) = -k_B T \ln Z$$

Z includes a sum over all microstates that
contribute to the macrostate X !

(A)	STATE	WEIGHT
X_1	1	$e^{-\beta \epsilon_1}$
	2	$e^{-\beta \epsilon_2}$
