- Electrical charges are quantized in the form of electrons and protons, nothing is smaller than  $\pm e$ .
- Classical Physics predicts that the intensity of radiation from blackbody-like sources goes to infinity with decreasing wavelength, which is experimentally shown to be untrue and is impossible anyway.
- Planck uses a mathematical trick for the first time ever-energy quantization: E = hf to "fix" the equations.

- Electrical charges are quantized in the form of electrons and protons, nothing is smaller than  $\pm e$ .
- Classical Physics predicts that the intensity of radiation from blackbody-like sources goes to infinity with decreasing wavelength, which is experimentally shown to be untrue and is impossible anyway.
- Planck uses a mathematical trick for the first time ever-energy quantization: E = hf to "fix" the equations.
- Einstein takes this result at face value and shows that photons are quantized in the same way, explaining the photoelectric effect.

- Electrical charges are quantized in the form of electrons and protons, nothing is smaller than  $\pm e$ .
- Classical Physics predicts that the intensity of radiation from blackbody-like sources goes to infinity with decreasing wavelength, which is experimentally shown to be untrue and is impossible anyway.
- Planck uses a mathematical trick for the first time ever-energy quantization: E = hf to "fix" the equations.
- Einstein takes this result at face value and shows that photons are quantized in the same way, explaining the photoelectric effect.
- Bohr adapts the idea of quantization to "explain" the Rydberg equation and why the emission/absorption spectrum is quantized. He quantizes angular momentum.

A new truth

Energy is quantized.

The 4 000-K curve has a peak near the visible range. This curve represents an object that would glow with a yellowish-white appearance. Thermal radiation of a body depends upon the temperature and wavelength.

Physics 280 Quantum Mechanics Lecture

< E >

The 4 000-K curve has a peak near the visible range. This curve represents an object that would glow with a yellowish-white appearance.

Thermal radiation of a body depends upon the temperature and wavelength.

We use blackbody radiation as a proxy for the more complex thermal radiation.

The 4 000-K curve has a peak near the visible range. This curve represents an object that would glow with a yellowish-white appearance.

Thermal radiation of a body depends upon the temperature and wavelength.

We use blackbody radiation as a proxy for the more complex thermal radiation.

**Wien's law** can explain the shift of the peak leftwards with temperature.

 $\lambda_{max}T = (0.2898 \times 10^{-2}) \text{ mK}$ 

Physics 280 Quantum Mechanics Lecture

Review of Early Quantum Mechanics

## Why we can approximate some glowing bodies as blackbody radiation

Dr. lones

The classical theory (red-brown curve) shows intensity growing without bound for short wavelengths, unlike the experimental data (blue curve). **Stefan's law** predicts the power emitted by blackbody radiation:

$$P = \sigma A e T^4$$

Image: A math a math

The classical theory (red-brown curve) shows intensity growing without bound for short wavelengths, unlike the experimental data (blue curve).

**Stefan's law** predicts the power emitted by blackbody radiation:

$$P = \sigma A e T^4$$

Combining these laws yields the **Rayleigh-Jeans** prediction:

$$I(\lambda,T)=\frac{2\pi ck_BT}{\lambda^4}$$

Dr. lones

The classical theory (red-brown curve) shows intensity growing without bound for short wavelengths, unlike the experimental data (blue curve).

**Stefan's law** predicts the power emitted by blackbody radiation:

$$P = \sigma A e T^4$$

Combining these laws yields the **Rayleigh-Jeans** prediction:

$$I(\lambda,T) = \frac{2\pi c k_B T}{\lambda^4}$$

Classical physics could take us no further, and it was wrong.

Dr. Jones Physics 28

Physics 280 Quantum Mechanics Lecture

#### The Ultraviolet Catastrophe: Resolved Reluctantly

Planck's leap: Supposing that blackbody radiation was emitted by 'resonators', these resonators could only have energy in discreet quantity:

$$E_n = nhf$$

A (1) > A (1) > A

#### The Ultraviolet Catastrophe: Resolved Reluctantly

Planck's leap: Supposing that blackbody radiation was emitted by 'resonators', these resonators could only have energy in discreet quantity:

$$E_n = nhf$$

*n* is a positive integer, the **quantum number**, f is frequency of vibration, *h* is a new constant he fit to experimental results:

$$h = 6.626 \times 10^{-34} \mathrm{J} \cdot \mathrm{s}$$

#### The Ultraviolet Catastrophe: Resolved Reluctantly

Planck's leap: Supposing that blackbody radiation was emitted by 'resonators', these resonators could only have energy in discreet quantity:

$$E_n = nhf$$

*n* is a positive integer, the **quantum number**, f is frequency of vibration, *h* is a new constant he fit to experimental results:

$$h = 6.626 \times 10^{-34} \mathrm{J} \cdot \mathrm{s}$$

$$I(\lambda, T) = \frac{2\pi hc^2}{\lambda^5 \left( e^{\frac{hc}{\lambda k_B T}} - 1 \right)}$$

• Quantization of energy solved the Blackbody Radiation problem and the Photoelectric Effect. It solved the scattering problem (Compton effect) and although nobody could quite make sense of it,

- Quantization of energy solved the Blackbody Radiation problem and the Photoelectric Effect. It solved the scattering problem (Compton effect) and although nobody could quite make sense of it,
- Another mystery dominated atomic physics-nobody could explain the spectra of gasses.

- Quantization of energy solved the Blackbody Radiation problem and the Photoelectric Effect. It solved the scattering problem (Compton effect) and although nobody could quite make sense of it,
- Another mystery dominated atomic physics-nobody could explain the spectra of gasses.
- We might expect a continuous distribution of wavelengths, but instead we find discrete line spectrum called the *emission spectrum*.

- Quantization of energy solved the Blackbody Radiation problem and the Photoelectric Effect. It solved the scattering problem (Compton effect) and although nobody could quite make sense of it,
- Another mystery dominated atomic physics-nobody could explain the spectra of gasses.
- We might expect a continuous distribution of wavelengths, but instead we find discrete line spectrum called the *emission spectrum*.
- Passing white light through gasses result in discrete missing wave- lengths, this is called the absorption spectrum.

• Example emission (hydrogen, mercury, and neon) and absorption spectrum for hydrogen:

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・ ・

• Example emission (hydrogen, mercury, and neon) and absorption spectrum for hydrogen:

• 19th century physicists can't explain these spectra.

• Balmer found an empirical equation that correctly predicted the wavelengths of four of the visible emission lines; Rydberg expanded this equation to find all emission lines:

$$\frac{1}{\lambda} = R_H \left( \frac{1}{2^2} - \frac{1}{n^2} \right), \quad n = 3, 4, 5, \cdots$$

• Balmer found an empirical equation that correctly predicted the wavelengths of four of the visible emission lines; Rydberg expanded this equation to find all emission lines:

$$\frac{1}{\lambda} = R_H \left( \frac{1}{2^2} - \frac{1}{n^2} \right), \ n = 3, 4, 5, \cdots$$

•  $R_H$  is a constant called the Rydberg constant and is equal to  $1.0973732 \times 10^7 m^{-1}$ .

• Balmer found an empirical equation that correctly predicted the wavelengths of four of the visible emission lines; Rydberg expanded this equation to find all emission lines:

$$\frac{1}{\lambda} = R_H \left( \frac{1}{2^2} - \frac{1}{n^2} \right), \ n = 3, 4, 5, \cdots$$

- $R_H$  is a constant called the Rydberg constant and is equal to  $1.0973732 \times 10^7 m^{-1}$ .
- The shortest wavelength is found when  $n \rightarrow \infty$  is called the series limit with wavelength 364.6 nm (ultraviolet).

Other physicists started experimenting with these numbers and found similar equations that described other lines in the spectrum:

Lyman series: 
$$\frac{1}{\lambda} = R_H \left( 1 - \frac{1}{n^2} \right), \quad n = 2, 3, 4, \cdots$$
  
Paschen series:  $\frac{1}{\lambda} = R_H \left( \frac{1}{3^2} - \frac{1}{n^2} \right), \quad n = 4, 5, 6, \cdots$   
Bracket series:  $\frac{1}{\lambda} = R_H \left( \frac{1}{4^2} - \frac{1}{n^2} \right), \quad n = 5, 6, 7, \cdots$ 

It all works very well, but nobody knows why.

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・ ・

臣

A physicists named Niels Bohr saw that energy quantization had solved the blackbody and photoelectric problem, and he wondered if it could solve the mystery of the atomic spectrum lines as well. Here is a basic outline of his reasoning.

• Assume the classical model of the electron orbiting the nucleus of the hydrogen atom under electrical forces. In this case the total energy is

$$E = K + U = \frac{1}{2}m_ev^2 - k_e\frac{e^2}{r}$$

and since we assume the electron is going in a circle, the electric force must act as a centripetal force:

$$\frac{k_e e^2}{r^2} = \frac{m_e v^2}{r} \implies v^2 = \frac{k_e e^2}{m_e r}$$

Using this value for velocity, we have kinetic energy:

$$K = \frac{1}{2}m_e v^2 = \frac{k_e e^2}{2r} \text{ and } E = -\frac{k_e e^2}{2r}$$

• Assume the classical model of the electron orbiting the nucleus of the hydrogen atom under electrical forces. In this case the total energy is

$$E = K + U = \frac{1}{2}m_ev^2 - k_e\frac{e^2}{r}$$

and since we assume the electron is going in a circle, the electric force must act as a centripetal force:

$$\frac{k_e e^2}{r^2} = \frac{m_e v^2}{r} \implies v^2 = \frac{k_e e^2}{m_e r}$$

Using this value for velocity, we have kinetic energy:

$$K = \frac{1}{2}m_e v^2 = \frac{k_e e^2}{2r} \quad \text{and} \quad E = -\frac{k_e e^2}{2r}$$

• So far, so classical.

A (1) > (1) > (1)

• Next comes the quantum step. Assume that only certain orbits are stable (called *stationary states*, which validates are previous assumption of using classical physics). The atom emits radiation when it makes a *quantum leap* from one state to another. The change in its energy after making this leap is *quantized*:

 $E_f - E_i = hf$ , positive value means absorbed, negative value means en

 Bohr next a new leap: quantizing the electron's orbital angular momentum:

$$m_e vr = n \frac{h}{2\pi} = n\hbar$$

where  $\hbar = h/2\pi$ . The energy quantization was enough to fluster some, but this latter assumption was a radically new expansion of the concept of quantization.

• □ > • □ > • □ > • □ > • □ >

 Bohr next a new leap: quantizing the electron's orbital angular momentum:

$$m_e vr = n \frac{h}{2\pi} = n\hbar$$

where  $\hbar = h/2\pi$ . The energy quantization was enough to fluster some, but this latter assumption was a radically new expansion of the concept of quantization.

• Now lets apply this radical concept:

$$v^2 = \frac{n^2 \hbar^2}{m_e^2 r^2} = \frac{k_e e^2}{m_e r} \implies r_n = \frac{n^2 \hbar^2}{m_e k_e e^2}, \ n = 1, 2, 3$$

• □ > • □ > • □ > • □ > • □ >

• Call the orbit with the smallest radius the Bohr radius (when n = 1):

$$a_0=\frac{\hbar^2}{m_ek_ee^2}=0.0529nm$$

Plug this all back into the energy equation to find:

$$E_n = -\frac{k_e e^2}{2a_o} \left(\frac{1}{n^2}\right), \ n = 1, 2, 3, \cdots$$

or numerically:

$$E_n = -\frac{13.606 eV}{n^2}, \ n = 1, 2, 3, \cdots$$

Now let's find out the frequency of light emitted from a quantum leap:

$$f = \frac{E_i - E_f}{h} = \frac{k_e e^2}{2a_0 h} \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right)_{\text{Binder}}$$

• That looks familiar ...

$$\frac{1}{\lambda} = \frac{f}{c} = \frac{k_e e^2}{2a_0 hc} \left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

Plugging in all of our numbers:

$$\frac{k_e e^2}{2a_0 hc} = 1.0973732 \times 10^7 m^{-1} = R_H$$

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・ ・

That looks familiar...

$$\frac{1}{\lambda} = \frac{f}{c} = \frac{k_e e^2}{2a_0 hc} \left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

Plugging in all of our numbers:

$$\frac{k_e e^2}{2a_0 hc} = 1.0973732 \times 10^7 m^{-1} = R_H$$

• Quantum mechanics had **theoretically** predicted the value of *R*<sub>*H*</sub>. At this point, attempts to rescue classical physics were beginning to look hopeless.

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

That looks familiar...

$$\frac{1}{\lambda} = \frac{f}{c} = \frac{k_e e^2}{2a_0 hc} \left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

Plugging in all of our numbers:

$$\frac{k_e e^2}{2a_0 hc} = 1.0973732 \times 10^7 m^{-1} = R_H$$

- Quantum mechanics had **theoretically** predicted the value of *R*<sub>*H*</sub>. At this point, attempts to rescue classical physics were beginning to look hopeless.
- We see it again: integers describing physical reality-one of the key signatures of quantum mechanics. This made most physicists uncomfortable, but also energized by the revolutionary spirit in the air.

• Planck predicts quantization (1900): *E* = *nhf*, solves ultraviolet catastrophe

イロト イヨト イヨト イヨト

臣

- Planck predicts quantization (1900): *E* = *nhf*, solves ultraviolet catastrophe
- Einstein proposes that light is quantized (1905), solved photo-electric effect

- Planck predicts quantization (1900): *E* = *nhf*, solves ultraviolet catastrophe
- Einstein proposes that light is quantized (1905), solved photo-electric effect
- Bohr proposes electron orbital angular momentum is quantized (1913), solves hydrogen spectrum problem,  $E_n = \frac{-13.606\text{eV}}{n^2}$

- Planck predicts quantization (1900): *E* = *nhf*, solves ultraviolet catastrophe
- Einstein proposes that light is quantized (1905), solved photo-electric effect
- Bohr proposes electron orbital angular momentum is quantized (1913), solves hydrogen spectrum problem,  $E_n = \frac{-13.606\text{eV}}{n^2}$
- de Broglie (1923/24) proposes that if photons are waves and particles, so are massive particles like electrons:

$$p = mv = rac{E}{c} = rac{hf}{c} = rac{h}{\lambda} \rightarrow \lambda = rac{h}{mv}$$

 If particles are waves, how do we discuss their amplitudes and displacements like we do for classical waves? We need some sort of wave function to do so, which we write as Ψ.

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

- If particles are waves, how do we discuss their amplitudes and displacements like we do for classical waves? We need some sort of wave function to do so, which we write as Ψ.
- For light, the intensity of the wave is proportional to the square of the electric field. The more intense the light, the more photons we can find, and so the number of photons is proportional to the intensity is proportional to the square of the electric field (the EM wave amplitude).

- If particles are waves, how do we discuss their amplitudes and displacements like we do for classical waves? We need some sort of wave function to do so, which we write as Ψ.
- For light, the intensity of the wave is proportional to the square of the electric field. The more intense the light, the more photons we can find, and so the number of photons is proportional to the intensity is proportional to the square of the electric field (the EM wave amplitude).
- Put another way, the square of the electric field amplitude is proportional to the probability that we will find a photon at a certain region.

• □ > • □ > • □ > • □ > • □ >

• Schrödinger found the equation that properly describes how these matter waves behave:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} + U\psi = E\psi$$

- This is called the Schrödinger equation.
- For most particles, we can separate the time-dependence so that

$$\Psi(r,t)=\psi(r)e^{-i\omega t}$$

• Schrödinger found the equation that properly describes how these matter waves behave:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2}+U\psi=E\psi$$

- This is called the Schrödinger equation.
- For most particles, we can separate the time-dependence so that

$$\Psi(\mathbf{r},t)=\psi(\mathbf{r})e^{-i\omega t}$$

• This is a **probabilistic equation**, where the probability of finding a particle whose wave is  $\psi$  within any given region of space is  $P(x, y, z)dV = |\psi|^2 dV$ .

• Schrödinger found the equation that properly describes how these matter waves behave:

- This is a **probabilistic equation**, where the probability of finding a particle whose wave is  $\psi$  within any given region of space is  $P(x, y, z)dV = |\psi|^2 dV$ .
- What is matter then? A particle? A wave? Is  $\psi$  the true manifestation of matter?

- $\psi$  is the true manifestation of matter.

For any probability function, the integral of the entire function over infinity must be equal to one:

$$\int_{-\infty}^{+\infty} |\psi(x)|^2 \, dx = 1$$

For any probability function, the integral of the entire function over infinity must be equal to one:

$$\int_{-\infty}^{+\infty} |\psi(x)|^2 \, dx = 1$$

It can be show that the "standard deviation in the results of repeated measurements on identically prepared systems", or the "uncertainty", has the following relation:

$$\Delta x \Delta p \geq \frac{\hbar}{2}$$

For any probability function, the integral of the entire function over infinity must be equal to one:

$$\int_{-\infty}^{+\infty} |\psi(x)|^2 \, dx = 1$$

It can be show that the "standard deviation in the results of repeated measurements on identically prepared systems", or the "uncertainty", has the following relation:

$$\Delta x \Delta p \geq \frac{\hbar}{2}$$

This is the Heisenberg Uncertainty Principal.

The wave function is sinusoidal in regions I and III, but is exponentially decaying in region II.

When there is a barrier which has too much energy for a particle to pass through in terms of classical physics, quantum mechanics correctly predicts that there is still a probability it will pass through. This is called **tunneling**. The wave functions  $\psi$  for a particle in a potential well of finite height with n = 1, 2, and 3

The probability densities  $|\psi|^2$  for a particle in a potential well of finite height with n = 1, 2, and 3

#### **Proton-Proton Fusion**

This is the nuclear <u>fusion process</u> which fuels the <u>Sun</u> and other stars which have core temperatures less than 15 million Kelvin. A <u>reaction cycle</u> yields about 25 MeV of energy.
